1. Introduction

The homogeneous catalytic functionalization of various skeletons, among them biologically important ones, is an efficient method for the synthesis of new derivatives [1–3]. There is an increasing interest in developing new strategies to introduce functional groups into specific positions of the steroidal nuclei in order to modify their biological properties. Transition metal catalyzed reactions are versatile tools both for the construction of the steroidal framework from easily available building blocks and for the functionalization of the steroidal skeleton [4].

The ester and carboxamide functionalities (especially at the distinguished position-17 or 3 of an estrene [5–8] or androstane skeleton [9–11]) proved to be efficient moieties in pharmacologically important derivatives and can be obtained in palladium-catalyzed reactions. Although the functionalization of the A and D ring of the steroidal skeleton is straightforward also in other homogeneous catalytic reactions (cross-coupling, dihydroxylation, hydroformylation, etc.) [4], to the best of our knowledge, no examples for the carbonylation reactions or any other carbon-carbon bond forming reactions at the sterically hindered positions (C-11 and C-12) of the C-ring are known.

In the present paper, we report on the efficient synthesis of steroids possessing 12-carboxamido-11-ene moiety in palladium-catalyzed carbonylation of an ‘iodo-vinyl’ substrate bearing 12-iodo-11-ene functionality. The application of the
easily accessible iodo-alkenes [12,13] as substrates provides an approach for the synthesis of 12-functionalized steroids of potential practical importance.

2. Experimental

PPh₃ and 1,1,3,3-tetramethylguanidine (TMG) were purchased from Aldrich. Hecogenin was obtained from the Gedeon Richter Pharmaceutical Work Ltd., Commercial Et₃N, primary and secondary amines (Aldrich) were used without further purification. Toluene, DMF, and the alcohols were dried according to standard procedures.

The steroidal 12-ido-11-ene (3) was synthesized according to an analogous method [13] by using the 12-keto derivative (1). It was converted into the corresponding hydrazone (2) that was treated with iodine in the presence of TMG resulting in (3).

Owing to differences to the previously published methods, a residue was heated at 90°C for an hour. Then the solvent was evaporated and the temperature. After the addition was completed, the mixture was stirred for 6 h. (The composition of the reaction mixture was checked by TLC.) The solvent was evaporated to dryness, and the rest was dissolved in 10 ml chloroform. It was washed with 15 ml portions of water (twice), 5% hydrochloric acid and brine. The organic layer was separated, dried on sodium sulfate and evaporated. The chromatography (silicagel, ethanol/chloroform = 1/1) resulted in the 12-carboxyl derivative (4).

The steroidal 12-ido-11-ene (3) was synthesized according to an analogous method [13] by using the 12-keto derivative (1). It was converted into the corresponding hydrazone (2) that was treated with iodine in the presence of TMG resulting in 3. Owing to differences to the previously published methods, a detailed description of the synthesis will be given below.

The ¹H and ¹³C NMR spectra were recorded on a VARIAN INOVA 400 spectrometer at 400 and 100.58 MHz, respectively. The chemical shifts are given as  δ values (ppm), with tetramethylsilane as the internal standard. TLC analyses were carried out by using Merck TLC sheets (Silica gel 60 F254) and chloroform as well as chloroform/ethanol (19/1) as eluents.

Mass spectra were recorded on a Finnigan MAT 95 magnetic sector instrument equipped with a FAB ion source. The Cs⁺ ion gun was used at 20 keV and the matrix was glycerol.

2.1. Synthesis of 3β-hydroxy-12-iodo-5α,25R-spirost-11-ene (3)

Hecogenin (1) (4 g, 9.29 mmol), freshly distilled hydrazine hydrate (98%, 40.24 g, 0.81 mol) and barium oxide (40 mg) in ethylene glycol (150 ml) were heated for 4 days at 160°C. After completion of the reaction the mixture was poured onto water and extracted with dichloromethane. Then the organic phase was dried over sodium sulfate, and evaporated to give 2.55 g (52.5%).

A mixture of iodine (6.08 g, 23.92 mmol) in ether (20 ml) was added dropwise at room temperature. The 1H NMR (CDCl₃, 400 MHz): 6.16 (br s, 1H, 11-C) f = 0.53 (CHCl₃); 79.5; 71.0; 66.9; 61.2; 60.7; 54.5; 51.7; 44.3; 41.6; 37.8; 36.1; 35.9; 33.2; 31.8; 31.4; 32.3; 30.3; 28.2; 28.8; 19.0; 17.0; 15.8; 13.0; MS (m/z): 541 (M⁺); 523, 481, 413, 397. Analysis calculated for C₂₇H₄₁IO₃: C, 60.00; H, 7.65. Found: C, 60.11; H, 7.52.

2.2.2. Analytical and spectroscopic data of compounds

A mixture of 3 (300 mg, 0.55 mmol), palladium(II) acetate (5.6 mg, 0.025 mmol), and triphenylphosphine (13.1 mg, 0.05 mmol) were dissolved in 10 ml aqueous DMF (containing 1% water) and triethylamine (0.5 ml) under argon. The atmosphere was changed to carbon monoxide (1 bar), and the reaction was conducted at 50°C for 6 h. (The composition of the reaction mixture was checked by TLC.) The solvent was evaporated to dryness, and the rest was dissolved in 10 ml chloroform. It was washed with 15 ml portions of water (twice), 5% hydrochloric acid and brine. The organic layer was separated, dried on sodium sulfate and evaporated.

The 1H NMR (CDCl₃, 400 MHz): 171.0 (M, 100.58 MHz, CDCl₃): 141.4 (11-C); 120.0 (12-C); 109.0 (22-C); 80.0; 71.3; 67.1; 60.2; 57.7; 54.4; 45.0; 43.5; 38.2; 36.5; 36.3; 33.1; 32.2; 31.4; 30.8; 30.5; 30.2; 29.9; 29.2; 29.1; 19.3; 17.3; 15.0; 13.6. Analysis calculated for C₂₈H₄₁O₅: C,

3. Results and discussion

As a part of our ongoing interest in the homogeneous catalytic functionalization of steroids, the introduction of a functional group into position-12 was carried out. The 12-iodo-11-ene derivative, obtained by the transformation of the 12-keto-functionality of hecogenin (1) via its hydrazone (2), was chosen as model compound for carbonylation reactions (Fig. 1). The 12-iodo-11-ene derivative (3β-hydroxy-12-iodo-5α,25R-spirorost-11-ene, 3) was reacted with carbon monoxide and various primary and secondary amines as N-nucleophiles (tert-butylamine, aniline, diethylamine, pyperidine, morpholine, methyl alaninate or methyl prolinate) or O-nucleophiles (methanol or ethanol) in DMF in the presence of palladium—phosphine 'in situ' catalysts. (The 'in situ' formation of highly active coordinatively unsaturated Pd(0) catalysts with monobidentate phosphines has been published before [14].) The corresponding 12-carboxamido-11-ene derivatives (3β-hydroxy-12-N-tert-butyl-carboxamido-5α,25R-spirorost-11-ene (7), 3β-hydroxy-12-N-phenyl-carboxamido-5α,25R-spirorost-11-ene (8), 3β-hydroxy-12-N,N-diethyl-carboxamido-5α,25R-spirorost-11-ene (9), 3β-hydroxy-12-N,N-(1′,5′-pentadiyl)carboxamido-5α,25R-spirorost-11-ene (10), 3β-hydroxy-12-N,N-(1′,5′-3-oxapentadiyl)carboxamido-5α,25R-spirorost-11-ene (11), 3β-hydroxy-12-N-(1′-methoxycarbonyl-ethyl)-carboxamido-5α,25R-spirorost-11-ene (12), 3β-hydroxy-12-N,N-(1′′-methoxycarbonyl-1′,4′-butadiyl)-carboxamido-5α,25R-spirorost-11-ene (13)) were synthesized in moderate to good yields depending on the structure of the amine (Table 1). The lowest yield was obtained with the less basic aniline (35%), while the highest with tert-butyl-amine and methyl alaninate (92 and 90%, respectively). The application of secondary amines (piperidine and methyl prolinate) resulted in slightly lower yields.

The formation of the carboxamides can be explained by the following reaction mechanism (Fig. 2). The palladium-alkenyl intermediate, which is formed in the oxidative addition of the ‘iodo-vinyl’ substrate onto the ‘in situ’ formed palladium(0) species, insert carbon monoxide resulting in a palladium-acyl complex. The highly reactive acyl intermediate undergoes aminolysis with the primary or secondary amine yielding the corresponding carboxamide in the product-forming step.

Using alcohols (methanol, ethanol) as nucleophiles instead of the amines, ester functionality can be introduced into the

b Yields obtained after chromatography.
The further functionalities of one of the hindered positions (position 12) can be functionalized in moderate to good yields without any side reactions. The strength of the homogeneous carbonylation reaction was shown by the fact that even iodooalkenes as substrates can be utilized iodoalkenes as substrates. The strength of the homogeneous carbonylation reaction of easily available carboxamides can be synthesized in yields of practical interest under reaction conditions conjugated unsaturated steroidal 12-derivative 

![Diagram](image)

Fig. 2 - A simplified mechanistic representation of the catalytic steps of aminocarbonylation.

Carrying out the alkoxycarbonylation reaction with 3 under similar conditions as the amino-carbonylation reaction, low conversions towards esters (12% and 10% for methyl and ethyl ester, respectively) have been obtained and their isolation as pure substance for full characterization failed. (The methyl and ethyl esters (5 and 6, respectively) have been detected by HPLC-MS only.)

Surprisingly, in the presence of alcohols 12-carboxylic acid derivative (4) has been obtained and isolated in yields up to 60% depending on the reaction conditions. (It has to be noted that carboxylic acids can be synthesized not only via the corresponding esters by hydrolysis but also in direct hydroxycarbonylation [10,15–17].) Similar steroidal acid (17-carboxy-5α-androstan-3β-ol) formation was already observed as an unexpected side-reaction with enol-sulfonates [18] and iodoalkenes [19]. In the latter case it was clarified that the corresponding carboxylic acids were produced via the primary formation of carboxylic anhydrides under carbonylation conditions in the presence of the water impurity of the solvent.

As a summary it can be stated, that under appropriate reaction conditions conjugated unsaturated steroidal 12-carboxamides can be synthesized in yields of practical interest in palladium catalyzed carbonylation reaction of easily available iodoalkenes as substrates. The strength of the homogeneuous carbonylation reaction was shown by the fact that even one of the hindered positions (position 12) can be functionalized in moderate to good yields without any side reactions of the further functionalities.
